Keeping time

Astronomy 101
Syracuse University, Fall 2021
Walter Freeman

September 23, 2021

And that inverted Bowl we call The Sky,
Whereunder crawling coop't we live and die,
Lift not thy hands to it for help – for It
Rolls impotently on as Thou or I.

–Omar Khayyám (1048-1131), translated into English by Edward FitzGerald (1859)

I'm cheating death
In Stellarium
I'm peeking ahead
To stars I will never see.

–Poetic text message from K. Alice Lindsay, used with permission

The crescent moon and Venus at sunset by Crouse College, by Astronomy 101 student ComradeWilhelm (Discord alias)

- Our printers are back alive. Prelab 4 will be available in the Physics Clinic by 5pm today.
- Quiz 1+2 is Tuesday:
  - We will post seating charts and send them out as PDF's ahead of time this time
  - Please bring a pencil and knowledge of your SUID

- Blackboard is having trouble; I have your scores on Quiz 1 and will post them tomorrow once Blackboard is working again

The full thing is on the website. In brief:

- Choose a historical calendar
- Research it
- Write on how it connects timekeeping to the cycles in the sky
- Due in three weeks (October 18)
- Potential for significant extra credit
- Some special assignments for particular calendars; read the whole thing

In *The Lord of the Rings*, Frodo and Sam traveled with Sméagol to Mordor. During part of their journey, they needed to hide from the Nazgûl, so they could only travel during absolute darkness – when neither the Sun nor the Moon were visible in the sky.

If the Moon was waxing gibbous, during what part of the day could they travel?

A: For a short time after sunset

B: For a short time before sunrise

C: During the first half of the night

D: During the last half of the night

In *The Lord of the Rings*, Frodo and Sam traveled with Sméagol to Mordor. During part of their journey, they needed to hide from the Nazgûl, so they could only travel during absolute darkness – when neither the Sun nor the Moon were visible in the sky.

If the Moon was waxing gibbous, during what part of the day could they travel?

A: For a short time after sunset

B: For a short time before sunrise

C: During the first half of the night

D: During the last half of the night

E: What's moonlight, precioussss?

Why are the changes in the seasons in *Game of Thrones* so terrifying?

Why are the changes in the seasons in *Game of Thrones* so terrifying?

... they're unpredictable!

We've long used the immutability of the sky as a symbol for constancy. The cycles of the Sun, Moon, and stars don't ever change, but some things do!

These unexpected things in the sky once terrified people; now we know why they happen.

Eclipses

You know that during a new moon, the Moon lies roughly between the Earth and the Sun.

However, the Moon's orbit is tilted just a bit, so it usually passes over or under the Sun.

If it passes in front, you get a solar eclipse!
This terrified many of the ancients – "the Sun got eaten! We're doomed!"

Eclipses

You know that during a full moon, the Earth lies roughly between the Moon and the Sun.

Same deal: usually the Earth's shadow misses the Moon. Sometimes it doesn't!

Here some light is refracted by the atmosphere. The blue component is scattered away by the atmosphere; the red component bends and hits the Moon.

Orbits of things in the Solar System are not always close to circular.

There are lots of small things in the Solar System, many of which have elongated orbits that sometimes cross ours.

Meteors:

- Little rocky or metallic bits of matter that orbit the Sun
- Sometimes they get to Earth and glow as atmospheric drag heats them
- Sometimes they hit the surface, and we get chunks of space-slag
- Historical cultures sometimes used them as easy access to metal

Comets are "dirty snowballs" whose orbits are *highly* elongated.

- Mostly made of ice
- When they get close to the Sun, the heat melts bits off of them
- This stream of stuff reflects sunlight and makes the comet's "tail"
- Historical cultures were often terrified of them, but they're just space-snowballs

The planets: semi-predictable

Demo on *Stellarium*

The planets: semi-predictable

Demo on *Stellarium*

Sometimes some planets appear to go backwards ("retrograde motion").

This tells us that celestial sphere model can't be literally true. Why does it work for everything else?

- The celestial sphere model works if things appear to only rotate around the Earth.
- The stars are so far away that only the Earth's rotation matters
- The Earth orbits the Sun, so we just pretend that the Sun is on a different sphere turning a bit slower, taking into account both our revolution around it and our rotation
- The Moon orbits the Earth, so we again put the Moon on a different sphere, turning slower
- ... but how can we get a sphere to go forwards and backwards?
- **The celestial sphere model gets the motion of the planets badly wrong**

Keeping time: the very predictable

The predictable cycles in the sky are the basis for the way we keep time.

One day

- Earth rotating around its axis

One year

- 365 days
- Earth's orbit around the Sun

Keeping time: the very predictable

The predictable cycles in the sky are the basis for the way we keep time.

One day

- Earth rotating around its axis

One year

- 365 days
- Earth's orbit around the Sun

One month

- One orbit of the Moon around the Earth

A reminder: Two sorts of day

The *sidereal day* is the amount of time it takes the Earth, and thus the celestial sphere, to rotate once.

One sidereal day → 360° rotation of the Earth

The *solar day* is the amount of time from solar noon to solar noon.

Since the Earth orbits the Sun, this requires more than 360° rotation:

- 360° plus a little extra, to compensate for the motion of the Earth around the Sun
- In my animation, with the "fast orbit", this is a lot more than 360°
- In the real world, the Earth moves only $1/365 \approx 1°$ around the Sun each day
- ... so in a solar day the Earth rotates:
  - 360° for the stars to rise and set once...
  - ... plus *one more degree* to compensate for the Earth's movement

One solar day → 361° rotation of the Earth

Solar day:

- 361° rotation of Earth
- The Sun returns to its same position (east/west)
- A bit more than a sidereal day → the stars move "too far"
- Exactly 24 hours

Sidereal day:

- 360° rotation of Earth
- The stars return to their same positions (exactly)
- A bit less than a solar day → the Sun moves "too little"
- Four minutes less than 24 hours

What about the moonth?

Is a lunar month...

- One complete cycle of phases of the Moon? (new moon to new moon)
- One orbit of the Moon around the Earth?

What about the moonth?

Is a lunar month...

- One complete cycle of phases of the Moon? (new moon to new moon)
- One orbit of the Moon around the Earth?

Same deal:

- Synodic month: One complete cycle of phases of the Moon (29.5 days)
- Sidereal month: One orbit of the Moon ("Moon in Libra → Moon in Libra" – 27.3 days)

What about the moonth?

Is a lunar month...

- One complete cycle of phases of the Moon? (new moon to new moon)
- One orbit of the Moon around the Earth?

Same deal:

- Synodic month: One complete cycle of phases of the Moon (29.5 days)
- Sidereal month: One orbit of the Moon ("Moon in Libra → Moon in Libra" – 27.3 days)
- Calendar month – it varies depending on the calendar!

What about the year?

Is a year...

- ... from winter solstice to winter solstice?
- ... One orbit of the Earth around the Sun? ("Sun in Sagittarius → Sun in Sagittarius")

What about the year?

Is a year...

- ... from winter solstice to winter solstice?
- ... One orbit of the Earth around the Sun? ("Sun in Sagittarius $\rightarrow$ Sun in Sagittarius")

What would have to happen for them to be different?

Is a year...

- ... from winter solstice to winter solstice?
- ... One orbit of the Earth around the Sun? ("Sun in Sagittarius → Sun in Sagittarius")

What would have to happen for them to be different?

The orientation of the Earth's tilt makes one rotation every 26,000 years.

Same deal:

- Tropical (seasonal) year: solstice to solstice
- Sidereal year: one orbit around the Sun; 1/26,000 less than a seasonal year

The year

Sidereal year

- One Earth orbit around Sun
- 365.26 24-hour days (1/26,000 *more* than a seasonal year)
- Sun returns to same place relative to stars

The day

Sidereal day

- One Earth rotation
- 23 hours 56 minutes (1/365 *less* than a solar day)
- Stars return to the same places in the sky

The moonth

Sidereal moonth

- One Moon orbit around Earth
- 27.3 days (about 1/12 *less* than a synodic moonth)
- Moon returns to same place relative to stars

The year

Sidereal year

- One Earth orbit around Sun
- 365.26 24-hour days (1/26,000 *more* than a seasonal year)
- Sun returns to same place relative to stars

Seasonal year

- One cycle of the seasons (solstice to solstice)
- 365.24 24-hour days (1/26,000 *less* than a sidereal year)
- Sun does not quite return to same place relative to stars!

The day

Sidereal day

- One Earth rotation
- 23 hours 56 minutes (1/365 *less* than a solar day)
- Stars return to the same places in the sky

Solar day

- Noon to noon / midnight to midnight
- 24 hours (1/365 *more* than a sidereal day)
- Stars do not return to the same places in the sky

The moonth

Sidereal moonth

- One Moon orbit around Earth
- 27.3 days (about 1/12 *less* than a synodic moonth)
- Moon returns to same place relative to stars

Synodic moonth

- One cycle of the Moon phases
- 29.5 days (about 1/12 *more* than a sidereal moonth)
- Moon returns to same place relative to stars

The year

Sidereal year

- One Earth orbit around Sun
- 365.26 24-hour days
- Sun returns to same place relative to stars

Seasonal year

- One cycle of the seasons (solstice to solstice)
- 365.24 24-hour days
- Sun does not quite return to same place relative to stars!

Difference caused by wobble of Earth's axis; seasonal year about 1/26,000 shorter

The day

Sidereal day

- One Earth rotation
- 23 hours 56 minutes
- Stars return to the same places in the sky

Solar day

- Noon to noon / midnight to midnight
- 24 hours
- Stars do not return to the same places in the sky

Difference caused by motion of Earth around Sun: solar day about 1/365 longer

The moonth

Sidereal moonth

- One Moon orbit around Earth
- 27.3 days
- Moon returns to same place relative to stars

Synodic moonth

- One cycle of the Moon phases
- 29.5 days
- Moon returns to same place relative to stars

Difference caused by motion of Earth and Moon around Sun: synodic moonth about 1/12 longer

How many solar days are in a seasonal year?

How many solar days are in a seasonal year?

How many synodic moonths are in a seasonal year?

Keeping time

How many solar days are in a seasonal year?

How many synodic moonths are in a seasonal year?

How many solar days are in a moonth?

How many solar days are in a seasonal year?
365.24 (ack, doesn't come out even)

How many solar days are in a seasonal year?
365.24 (ack, doesn't come out even)

How many synodic moonths are in a seasonal year?
364.24 / 29.5 = 12.35 (also doesn't come out even)

Building a calendar

How many solar days are in a seasonal year?
365.24 (ack, doesn't come out even)

How many synodic moonths are in a seasonal year?
364.24 / 29.5 = 12.35 (also doesn't come out even)

How many solar days are in a moonth?
29.5 (ack, doesn't come out even)

... what do we do?

How many solar days are in a seasonal year?
365.24 (ack, doesn't come out even)

How many synodic moonths are in a seasonal year?
364.24 / 29.5 = 12.35 (also doesn't come out even)

How many solar days are in a moonth?
29.5 (ack, doesn't come out even)

... what do we do? Two choices:

- Don't worry about it (Gregorian months aren't lined up with the moonths)

How many solar days are in a seasonal year?
365.24 (ack, doesn't come out even)

How many synodic moonths are in a seasonal year?
364.24 / 29.5 = 12.35 (also doesn't come out even)

How many solar days are in a moonth?
29.5 (ack, doesn't come out even)

... what do we do? Two choices:
- Don't worry about it (Gregorian months aren't lined up with the moonths)
- Intercalation: add extras (about one in four years is a leap year)
